

Problem Statement for Zenflix

The proposed system is an online video streaming platform that allows users to register, log in, create and manage multiple profiles under a single account, and stream video content seamlessly. Users can maintain personal details, watch videos, provide reviews, comments, and view feedback from other users. The system will also maintain a watch history for tracking previously viewed content.

The platform includes an intelligent recommendation feature powered by machine learning. The system will analyze user watch history, reviews, ratings, and comments to understand viewing behavior and preferences. Based on this analysis, personalized video recommendations will be generated and displayed on the home page to improve user engagement and enhance the viewing experience.

The platform includes an administrator module with full control over content management. Only administrators are authorized to add, modify, or delete videos and related information such as genres and categories. Strong authentication and access control mechanisms will ensure that unauthorized users cannot access restricted features.

The system must satisfy key non-functional requirements by providing uninterrupted video streaming with minimal lag, ensuring high availability, maintaining strong security standards, and delivering a responsive user interface across different devices and screen sizes. The goal is to provide users with a secure, efficient, personalized, and user-friendly entertainment experience.
